Abstract

Background: Physical activity programmes have been identified as a potential strategy for improving social and emotional wellbeing in at-risk youth, who have a prevalence of depression and low self-esteem exceeding the general population. Methods: A systematic search of six electronic databases (EMBASE, OVID MEDLINE, PsychINFO, PubMed, Scopus, and SPORTDiscus) was conducted to identify physical activity programmes designed to improve social and emotional wellbeing in at-risk youth. Results: Our search identified 15 studies, which reported the effects of three types of physical activity interventions (i.e. outdoor adventure, sport and skill-based and physical fitness programmes) on social and emotional wellbeing. While many of the interventions resulted in significant positive effects, the risk of bias was high in all of the included studies. Conclusion: Due to the mixed findings and the high risk of bias, it is difficult to determine the efficacy of physical activity programmes for improving social and emotional well being in at-risk youth.

Key Practitioner Message:

- Physical activity programmes have the potential to improve social and emotional wellbeing in at-risk youth, but more rigorous trials are needed to evaluate their effectiveness.
- As none of the studies included long-term follow-ups (i.e. greater than 12-months), it remains untested whether the benefits associated with participation in physical activity programmes are sustained once youth return to their daily routines.
- The quality of existing studies is poor and has not improved since earlier reviews.
- Physiological and psychosocial factors may explain the beneficial effects of physical activity programmes on social and emotional wellbeing in at-risk youth.
Clinicians working with at-risk youth are encouraged to consider specific physical activity programmes to support social and emotional wellbeing and general health in this group.

Key words: Activity level; health psychology; mental health; intervention; resilience
Introduction

There is strong evidence for the beneficial effects of physical activity on musculoskeletal health, cardiovascular health, and adiposity in youth (Strong, et al., 2005). In addition, an active lifestyle is associated with improved mental health in young people (Ekeland, Heian, & Hagen, 2005; Parfitt & Eston, 2005). It is therefore not surprising that physical activity programmes have been identified as a potential strategy for improving social and emotional wellbeing in ‘at-risk’ youth (Collingwood, 1997; MacMahon, 1990; West & Crompton, 2001), as these individuals are characterised by a number of conditions and psychopathologies, with a prevalence of depression and low-self-esteem exceeding the general population (Gendron, Royer, Bertrand, & Potvin, 2004; MacMahon, 1990).

‘At-risk’ or ‘disaffected’ youth are children and adolescents who live in a negative environment and/or do not possess the skills and values that assist them in becoming responsible members of society (Collingwood, 1997). Disaffection is a complex and multidimensional phenomenon that may manifest itself in different ways including disengagement from mainstream activities, disruptive or antisocial behaviour and involvement in criminal activity (Sandford, Armour, & Warmington, 2006). Disaffection may lead to social isolation and partly explain the low levels of participation in structured physical activity programmes observed among at-risk youth (Burton & Marshall, 2005; Duncan, Duncan, Strycker, & Chaumeton, 2002).

Existing physical activity programmes for such at-risk youth can be broadly classified into three groups: i) outdoor adventure programmes, ii) sport and skill-based programmes and iii) physical fitness programmes. The mechanisms by which the three types of programmes confer their benefits may differ and a description of their characteristics is necessary. Outdoor recreation programmes generally involve experiential learning and are based on the belief that learning and behaviour change can be achieved through direct experience (Gass, 1993;
Programmes generally involve a range of physical activities such as rock climbing, orienteering and canoeing and may involve camping trips away from families. A previous review examining the impact of adventure programmes for at-risk youth found strong evidence for a positive effect on self-concept (West & Crompton, 2001), but noted that the methodological quality of the included studies was poor.

Organised sport programmes provide youth with an opportunity to participate in team and individual sport competitions and may result in positive outcomes through developmentally appropriate designs and positive child-adult (parent/coach) relationships (Fraser-Thomas, Cote, & Deakin, 2005). Skill-based programmes are generally targeted toward younger children and are focused on the development of motor skills, rather than participation in sport. Although there is debate as to what sport programmes actually achieve (Sandford, et al., 2006), they do provide youth with an opportunity to accrue health benefits through physical exertion, develop pro-social behaviours through positive interactions with others and achieve skill mastery (Robinson, Rudisill, & Goodway, 2009). Several reviews have espoused the potential benefits of sport and skill-based interventions for at-risk youth (Fraser-Thomas, et al., 2005; Martinek & Hellison, 1997; Sandford, et al., 2006), however, their conclusions have been based on limited evidence from empirical studies.

Physical fitness programmes involve exercise (e.g., resistance training, aerobics and circuit training) designed specifically to improve health-related fitness (i.e., cardio-respiratory fitness, muscular fitness, flexibility and body composition). Participation in physical exercise has been found to have both immediate and long-term beneficial psychological effects (Ekeland, et al., 2005). For example, individuals often report feeling better after exercising and evidence from previous reviews suggest that exercise programmes may improve self-esteem and reduce depression in children and adolescents (Ekeland, et al., 2005; MacMahon, 1990).
Previous reviews reporting the effects of outdoor education (West & Crompton, 2001) and physical fitness (MacMahon, 1990) programmes in at-risk youth were published over ten years ago. More recent reviews of the potential benefits of sport and skill-based interventions for at-risk youth have been descriptive in nature and not included risk of bias assessments (Fraser-Thomas, et al., 2005; Sandford, et al., 2006). Therefore this review provides both an update of the existing literature, and a critical review of the three different types of physical activity programmes (i.e. outdoor education, sport and physical fitness) for at-risk youth. As such, the primary aim of this review is to describe the effectiveness of physical activity interventions to improve social and emotional wellbeing in at-risk youth. Social and emotional well being is a broad term that includes feelings, behaviour, relationships, goals and personal strengths necessary for positive health and well being. It includes an individual’s “ability to identify and understand one’s feelings, accurately read and comprehend emotional states in others, manage strong emotions and their expression, regulate one’s behaviour, develop empathy for others, and establish and sustain relationships” (Australian Institute of Health and Welfare, 2009, p. 60). A secondary aim is to evaluate the quality of existing studies and provide recommendations for future studies.

Identification of studies

The Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) statement (Moher, Liberati, Tetzlaff, & Altman, 2009) guided the conduct and reporting of this review. A systematic search of six electronic databases (EMBASE, OVID MEDLINE, PsychINFO, PubMed, Scopus, and SPORTDiscus) was conducted on the 21st December 2010. A professional librarian developed individualised search strategies for the different databases using combinations of the following key words: (child OR children OR adolescent OR youth OR young person OR juvenile OR teen OR teenager) AND (delinquent OR ‘at risk’ OR ‘high risk’ OR troubled OR antisocial OR disaffected OR depressed OR depression)
AND (physical activity OR exercise OR sport OR fitness OR recreation). Published articles in peer reviewed journals were considered for the review. In the first stage of the literature search, titles and abstracts of identified articles were checked for relevance and additional articles known to the authors were assessed for possible inclusion. In the second stage, full-text articles were retrieved and considered for inclusion. In the final stage, the reference lists of retrieved full-text articles were searched.

Criteria for inclusion/exclusion

Two authors independently assessed the eligibility of the studies for inclusion using the following criteria: (i) participants were aged 4 to 18 years, (ii) participants were disaffected or “at risk” youth, including those experiencing behavioural difficulties, (iii) study involved the implementation of an outdoor education, exercise, sport or sport skills intervention/programme using a randomised controlled trial, quasi-experimental design or a single group pre-test post-test design, (iv) included quantitative assessment of social and emotional wellbeing (e.g., depression, anxiety, self-concept, self-self-esteem, resilience), (v) published in English. Participants with eating disorders and diagnosed psychiatric conditions were not included in the review. Conference abstracts, dissertations, theses and articles published in non-peer reviewed journals were not included in the review.

Risk of bias assessment

Studies were assessed for ‘risk of bias’ using criteria adapted from the Consolidated Standards of Reporting Trials (CONSORT) statement by two authors independently (Moher, et al., 2010). A ‘risk of bias’ score for each study was completed on a 6-point scale by assigning a value of 0 (absent or inadequately described) or 1 (explicitly described and present) to each of the following questions listed: (i) Were the groups comparable at baseline on key characteristics (yes, if stratified baseline characteristics were reported and groups were similar; no, if study did not include baseline information or a control/comparison group)? (ii) Did the
study include a control group and was the process of randomization clearly described and adequately carried out (e.g. envelope or algorithm)? (iii) Did the study report a power calculation and was the study adequately powered to detect intervention effects? (iv) Were the assessors blinded to treatment allocation at baseline and posttest? (v) Did the study report the numbers of participants who completed baseline and follow-up assessments and did at least 80% of participants complete follow-up assessments? (vi) Did the study account for potential differences at baseline in the analyses? Studies that scored 0-2 were regarded as having a high risk of bias, studies that scored 3-4 were classified as having a medium risk of bias and those that scored 5-6 were classified as having a low risk of bias.

Results

Overview of studies

The flow of studies through the review process is reported in Figure 1. Our search identified 15 studies that evaluated the effects of physical activity programmes on social and emotional wellbeing in at-risk children and adolescents (Table 1). Seven studies evaluated the effects of outdoor adventure programmes (Bloemhoff, 2006; Cross, 2002; Green, Kleiber, & Tarrant, 2000; Kaiser, Smith, Heleski, & Spence, 2006; Minor & Elrod, 1994; Pommier & Witt, 1995; Wu & Hsieh, 2006), seven studies evaluated the effects of sport and skill-based interventions (Basile, Motta, & Allison, 1995; Bonnette, McBride, & Tolson, 2001; Goodway & Rudisill, 1996; Maiano, Ninot, Morin, & Bilard, 2007; Palermo, et al., 2006; Robinson, et al., 2009; Tester, Watkins, & Rouse, 1999) and two studies reported the effects of physical fitness programmes (Basile, et al., 1995; Collingwood, Sunderlin, & Kohl, 1994). The majority of studies evaluated the effects of programmes among older children and adolescents, however, two studies (Goodway & Rudisill, 1996; Robinson, et al., 2009) reported the effects of motor skill interventions in at-risk preschool children.

** Insert Figure 1 here**
Risk of bias assessment

The risk of bias was high in all of the included studies (Table 2). There was 94% agreement between authors on the risk of bias assessment criteria and full consensus was achieved after discussion. Few studies provided stratified baseline characteristics and four studies did not include a control group or comparison group (Collingwood, et al., 1994; Kaiser, et al., 2006; Tester, et al., 1999; Wu & Hsieh, 2006). Although a number of studies were randomised controlled trials (Basile, et al., 1995; Goodway & Rudisill, 1996; Minor & Elrod, 1994; Palermo, et al., 2006), only one study described the process of randomisation (Basile, et al., 1995). Six studies used quasi-experimental designs (Bloemhoff, 2006; Bonnette, et al., 2001; Cross, 2002; Green, et al., 2000; Maiano, et al., 2007; Robinson, et al., 2009). None of the studies reported power calculations to determine if their studies were adequately powered to detect their hypothesized effects. One study provided adequate information to determine whether or not assessors were blinded to treatment allocations (Cross, 2002). Few studies reported the number of participants who completed baseline and follow-up assessments. Finally, a number of studies did not adjust for baseline values in the analysis of intervention effects on social and emotional wellbeing.

Outdoor adventure programmes

Significant improvements in self-worth (Pommier & Witt, 1995), self-concept (Wu & Hsieh, 2006), resilience (Bloemhoff, 2006; Green, et al., 2000), perceptions of alienation and self-control (Cross, 2002) were observed. However, these findings should be treated with some caution, as three of the studies involved quasi-experiments with matched comparison groups (Bloemhoff, 2006; Cross, 2002; Green, et al., 2000) and one of the interventions did not include either a control or a comparison group (Wu & Hsieh, 2006). Two programmes...
did not improve social and emotional wellbeing (Kaiser, et al., 2006; Minor & Elrod, 1994). The duration of the adventure programmes ranged from four hours (Bloemhoff, 2006) to three months (Minor & Elrod, 1994). The adventure programmes included a range of activities including rock climbing, ropes courses, horse riding, orienteering, sailing and canoeing. Two of the courses included family training components to support positive family relationships (Minor & Elrod, 1994; Pommier & Witt, 1995).

Sport and skill-based programmes

Both interventions targeting at-risk preschool children focusing on the development of fundamental movement skills resulted in significant improvements in perceived physical competence (Goodway & Rudisill, 1996; Robinson, et al., 2009). While Tester and colleagues (1999) reported that the Singapore’s Sports Challenge International Programme improved self-esteem in at-risk children and adolescents, their failure to include a control group makes it difficult to determine the true intervention effect. Additional benefits were identified by Palermo and colleagues (2006) who found that a 10-month karate programme helped to improve temperament in children with social cognitive and disruptive behaviours. Two sport-based programmes targeting at-risk adolescent boys (Bonnette, et al., 2001) and adolescent boys with conduct disorders (Maiano, et al., 2007) did not significantly improve physical self-perceptions. Basile and colleagues (1995) compared the effects of a skill mastery intervention to a fitness programme and a no treatment control and found that neither programme significantly improved self-concept in children with behavioural disorders. The skill mastery programme provided participants with an opportunity to achieve mastery on a single motor task (i.e. basketball free throw) without substantial physical exertion.

Physical fitness programmes

Two studies reported the effects of physical fitness programmes for at-risk youth (Basile, et al., 1995; Collingwood, et al., 1994). Collingwood and colleagues (1994) reported
significant improvements in self-concept in a large sample of at-risk adolescents following their participation in the First Choice Fitness leaders programme. However, their failure to include a control group and the high risk of bias in this study, make it difficult to interpret the intervention effects. Alternatively, the fitness programme evaluated by Basile et al (1995) did not improve self-concept in a group of children with behavioural disorders. The fitness programme consisted of jogging and walking around the school playground for 20 minutes. The programme also incorporated an obstacle course and additional activities to facilitate participant involvement and motivation.

Discussion

The primary aim of this review was to describe the effectiveness of physical activity interventions to improve social and emotional wellbeing in at-risk youth. While the majority of studies included in this review did not assess their impact on direct indictors of mental health, outcomes such as self-concept (Ali, Fang, & Rizzo, 2010), self-esteem (Bolognini, Plancherel, Bettschart, & Halfon, 1996), and resilience (Masten, 2007) are considered to be important protective factors against mental illness. For example, resilience is strongly associated with social competence, a sense of purpose, self awareness, a sense of belonging, problem solving, and critical thinking (Masten, 2007). These outcomes are of particular importance for at-risk youth, who tend to have low levels of resilience and lack the social-emotional skills necessary to recover from adverse circumstances (Collingwood, 1997).

There is some evidence to suggest that outdoor adventure, sport and physical fitness programmes have the potential to improve social and emotional wellbeing in at-risk youth. However, these findings should be treated with caution due to the high risk of bias in all of the studies reviewed. Clinicians working with at-risk youth are encouraged to consider specific physical activity programmes to support social and emotional wellbeing and general health in this group. They should be aware of the conditions under which these programme
are likely to be of benefit to young people and vigilant to the potential for an absence of 
clinically significant effects.

Outdoor adventure programmes

Despite considerable heterogeneity in the types of interventions and study 
populations, it appears that outdoor adventure programmes have the potential to improve 
resilience and self-concept in at-risk youth. Of the seven adventure programmes included in 
this review, five resulted in significant improvements in measures of social and emotional 
wellbeing. Our findings are consistent with a previous review of adventure programs for at-
risk youth (West & Crompton, 2001), which found significant positive changes in self-
concept in 14 of the 16 studies reviewed. The authors concluded that outdoor education 
programmes may contribute to reducing the negative behaviours typically demonstrated by 
at-risk youth. While their findings were generally positive, the authors noted the high risk of 
bias in many of the studies and questioned the generalizability of the interventions, as most of 
the participants were white male adolescents.

It is not entirely clear which aspects of the outdoor adventure programmes are 
responsible for inducing psychological benefits and studies have included family components 
in addition to the adventure activities (Minor & Elrod, 1994; Pommier & Witt, 1995). 
Although outdoor adventure programmes are generally delivered in the wilderness, an 
unfamiliar environment is perhaps the most important aspect of the experience (Gass, 1993). 
Adventure programmes tend to include traditional therapy techniques, such as self-reflection, 
and journal writing to encourage participants to process their experiences (West & Crompton, 
2001). Calculated risk taking, the mastery of challenging tasks and positive social support 
from instructors and peers may explain the improvements in outcomes observed among at-
risk youth attending outdoor adventure programmes. Unfortunately, the unfamiliar settings 
necessary for many outdoor education programmes limits their availability for many youth,
who may not have access to such activities and locations. Furthermore, it remains untested whether the changes induced through participation in these programmes are sustained once youth return to their daily routines.

Sport and skill-based interventions

While there is a growing interest in using sport programmes to re-engage disaffected youth (Sandford, et al., 2006), empirical evidence supporting the utility of such programmes is limited. The current review identified only six sport-based programmes for at-risk youth, all with a high risk of bias. The Singapore Sports Challenge programme reported 44% and 18% improvements in self-esteem in at-risk children and adolescents, respectively. However, no details of a control group were reported and it is unclear how many of the young people were retained in the programme over the study period. The Singapore Sports Challenge was based on an Australian programme and involved four trained sporting mentors (two males and two females) working with 50 identified at-risk students. Using sport as the medium students were taught preparation for life skills, including realistic goal setting, strategies to address conflict resolution with peers and family, strategies to ask for adult support, stress management, and promoting positive social behaviours in the outdoor setting and in the classroom. In addition to the student programme, parents and teachers were involved in workshops to develop new skills and support the work completed by the mentors. A novel aspect of the programme was that the students continued to interact with mentors via the internet and the mentors returned to the schools for a minimum of three years. This level of ongoing support is unique to the Singapore Sports Challenge and may explain the strong positive results of the programme.

Palermo and colleagues (2006) evaluated a 10-month karate programme in a sample of children with social cognitive and disruptive behaviours. They found significant beneficial effects on domains of temperament and noted that the improvements were evident at home, in
the dojo and in school. The study participants were included in a larger karate class of typically developing youth who were unaware that the targeted children were involved in an intervention. While the programme included physical exertion and motor skill development, it also taught participants self-regulation, executive skills, goal-directed attention and concentration. This type of intervention has considerable potential for engaging disaffected youth and the combination of activity to develop fitness and self-discipline may explain the improvements in temperament observed in this group.

The early childhood years are considered to be the golden years of skill development and motor skill proficiency in childhood and adolescence is associated with a range of health benefits (Lubans, Morgan, Cliff, Barnett, & Okely, 2010). Two studies reported the positive effects of motor skill interventions on physical self-perception in at-risk preschool children (Goodway & Rudisill, 1996; Robinson, et al., 2009). The evidence suggests that interventions to improve motor skills in young children will also improve physical self-perceptions and may, in turn, influence general self-concept and self-esteem. The longer-term effects of motor skill programmes on psychological outcomes in young children are unknown, yet the short-term effects suggest that this type of intervention is clearly warranted.

Physical fitness programmes

Our review included only two physical fitness programmes for at-risk youth, but additional evidence for the beneficial effects of physical fitness programmes were published prior to our review cut-off date (i.e., 1990) (Hilyer, et al., 1982; MacMahon & Gross, 1988). and included in an earlier review (MacMahon, 1990). MacMahon (1990) reviewed studies which reported the effects of exercise programmes on psychological outcomes in delinquent adolescents. Whilst acknowledging that delinquent adolescents are a heterogeneous group, he concluded that intensive aerobic exercise programmes have the potential to induce clinically important improvements in self-esteem and depression. MacMahon and Gross (1988)
evaluated the effects of aerobic exercise on self-concept, depression and physical fitness in juvenile delinquents. Participation in the exercise program resulted in improved self-concept, mood, and fitness. Interestingly, improvements in psychological variables were not dependent on improved physical fitness. In another study involving youth offenders, Hilyer and colleagues (1982) evaluated the effects of a 20-week physical fitness program delivered by counsellors. Participants in the training programme reported significant improvements in social and emotional wellbeing at the completion of the study.

Not surprisingly, the fitness programme evaluated by Basile and colleagues (1995) did not have a beneficial effect on self-concept in a group of children with behavioural disorders. This intervention required the participants to jog and walk around a field for 20 minutes four times per week for four weeks. This type of exercise is unlikely to engage children and may result in children developing negative attitudes toward physical activity. Ideally physical fitness programmes should provide meaningful experiences for participants and provide opportunities for youth develop physical activity behavioural skills, such as self-monitoring, self-assessment and goal setting. Alternatively, Collingwood et al (1994) reported beneficial intervention effects on self-concept in their large physical fitness leaders programme for at-risk youth. The objective of the First Choice programme was to provide alternative activities for at-risk youth that directly teach self-esteem, self-discipline and self-responsibility through physical activity (Collingwood, et al., 1994). The programme included three major components- youth fitness skills training programme, parent training module and peer fitness leader’s training. Although the study findings are compromised by methodological weaknesses, the strategy of using at-risk youth as physical fitness leaders has considerable promise. Unlike the First Choice programme which found that changes in fitness were associated with changes in psychosocial outcomes, MacMahon and colleagues (1988) found that improvements in psychological variables were not dependent on
improvements in physical fitness in an aerobic training programme for delinquent males. These findings suggest that there are multiple mechanisms responsible for improvements in social and emotional wellbeing in physical fitness programmes. Physiological hypotheses suggest that improvements in social and emotional wellbeing following exercise are due to changes in neurotransmitters such as noradrenalin or serotonin (MacMahon, 1990). Elevated endorphin levels induced by exercise bouts have been linked to several psychological and physiological changes, including changes in mood and exercise-induced euphoria (Harber & Sutton, 1984). Alternatively, psychological theories propose that physical fitness programmes provide individuals with a sense of achievement and mastery of body function which is associated improved wellbeing and self-esteem (MacMahon, 1990; Soenstroem & Morgan, 1989).

Risk of bias assessment

The risk of bias was high in all of the physical activity programmes reviewed. The quality of studies has not improved since earlier reviews of exercise (Ekeland, et al., 2005) and adventure programmes (West & Crompton, 2001), both of which, identified the methodological weaknesses of the included studies. Five of the 15 studies were randomised controlled trials and only one of these studies adequately described the process of randomisation. It was of additional concern that none of the studies included a power calculation to determine if their study was adequately powered to determine the hypothesized effects. Statistical significance is largely dependent upon sample size and future studies are encouraged to provide this information along with standardised intervention effect sizes using Cohen’s $d$. The retention of study participants was rarely described and this has important implications for determining the efficacy of the evaluated programmes. For example, if a large percentage of participants withdraw from the intervention and the data are not analysed
using intention-to-treat principles, researchers may conclude that the intervention worked even though many participants were dissatisfied with the programme.

**Potential mechanisms of physical activity on psychological wellbeing**

Knowledge regarding the mechanisms responsible for the effects of physical activity programmes on psychological wellbeing is limited (Cerin, 2010). Physiological mechanisms, such as alterations in fitness, neurotransmitters and endorphin levels (MacMahon, 1990), along with improvements in self-control, self-mastery and positive social support may be the possible mechanisms explaining the beneficial effects of physical activity programmes on social and emotional wellbeing in at-risk youth. Unfortunately we were not able to determine the different intervention components (e.g. additional therapy) necessary for inducing improvements in psychological outcomes. We encourage researchers working in this area to consider the different intervention components and test the potential mechanisms using mediation analysis.

**Strengths and limitations**

To the authors’ knowledge this is the first study to systematically review the impact of physical activity programmes on social and emotional wellbeing in at-risk youth. Due to the small number of studies and large heterogeneity in terms of study length, sample size, assessment of outcomes and participants, it was not possible, or desirable to conduct a meta-analysis of the included studies. The review was guided by the PRISMA statement and studies were assessed for risk of bias using criteria adapted from the CONSORT statement. Despite these strengths, there are some limitations that should be noted. First, our review did not include studies published before 1990, thus decreasing the pool of eligible studies. Studies published before this time, were not included because their results had been reported in previous reviews and their methodological weaknesses would potentially compromise the validity of our findings. Second, there is possible bias in the selection of studies because we
did not include abstracts, theses or studies published in non peer-reviewed journals. Third, there was considerable heterogeneity in the types of participants included in the review. Our predetermined definition of ‘at-risk’ was deliberately broad to include a wide range of studies and participants, including children and adolescents. Consequently, our review included programmes that targeted youth with clinical behavioural problems along with individuals classified as at-risk due to a variety factors (e.g. single-headed household, poverty, parental unemployment, low parental education, lack of stable home environment, parental drug exposure, incarceration of a parent and loss of parent/sibling). Finally, our criteria used to assess risk of bias were not extensive, the inclusion of additional items such as length of follow-up assessment and treatment of missing data should be considered for inclusion in future reviews.

Conclusions

While there have not been sufficient studies conducted to determine which types of programmes are most suitable for the various subgroups, there is evidence that adventure, sport and fitness programmes all have the potential to confer psychological benefits for at-risk youth. While individual preference may determine which type of programme is the most suitable for at-risk youth, it is recommended that clinicians recommend motor skill programs for younger children. Motor skills are ideally learnt in early childhood (Gallahue & Ozmun, 2006) and both actual and perceived competency are predictive of physical activity among children and adolescents (Lubans, et al., 2010; Wrotniak, Epstein, Dorn, Jones, & Kondilis, 2006). Young children considered at-risk may benefit from interventions to develop their motor skills, which may contribute to improved self-esteem in the physical domain. Sports programmes have many potential benefits for older children and adolescents (Fraser-Thomas, et al., 2005; Martinek & Hellison, 1997; Sandford, et al., 2006), yet the true effects of sport-
based programmes may not be easily captured in experimental studies, due to the difficulty of recruiting and retaining at-risk youth in programmes.

Finally, individuals working in child mental health practice are encouraged to recommend physical fitness programmes for older adolescents who may be at-risk. There is strong evidence to support the benefits of physical activity on physiological health in youth (Strong, et al., 2005) and some evidence to suggest that structured physical activity programmes contribute to social and emotional wellbeing in at-risk youth. Physical fitness programmes that provide meaningful challenges for individuals and an opportunity to improve fitness and apply behavioural skills (e.g. goal setting, self-monitoring and self-assessment) have demonstrated promise in promoting physical activity in the short-term (Lubans, Morgan, Callister, & Collins, 2009; Schneider-Jamner, Spruijt-Metz, Bassin, & Cooper, 2004).

Individuals who develop a routine of participating in lifetime activities (e.g. weight training, aerobics, circuit training etc.) that can be easily carried into adulthood are more likely to become active adults (Corbin, 2002) and participation in such programmes may act as a protective factor against mental illness in both the short and long-term.

Considering the high prevalence of depression and low-self-esteem in at-risk youth (Gendron, et al., 2004; MacMahon, 1990), their low rates of participation in structured physical activity programmes (Burton & Marshall, 2005; Duncan, et al., 2002) and the potential of such programmes to improve social and emotional wellbeing, encouraging at-risk youth to engage in physical activity programmes is justified. However, it remains untested whether the improvements in social and emotional wellbeing associated with participation in physical activity programmes are sustained once youth return to their daily routines. Until there is evidence for the long-term benefits of physical activity programmes, clinicians working with at-risk youth are encouraged to recommend physical activity programmes that promote sustainable physical activity behaviour change.
Acknowledgements

The authors would like to thank Sarah Costigan for her assistance in the preparation of this research paper.

Key points

- A physically active lifestyle is associated with improved mental health in young people.
- ‘At-risk’ or disaffected youth are characterised by a number of conditions and psychopathologies, with a prevalence of depression and low self-esteem exceeding the general population.
- Physical activity programmes have the potential to improve social and emotional wellbeing in at-risk youth, but more rigorous trials are needed to evaluate their effectiveness.
- Knowledge regarding the mechanisms responsible for the effects of physical activity programmes on psychological wellbeing is limited and should be explored in future trials.
- As the long-term effects of existing programmes have not been tested, clinicians working with at-risk youth are encouraged to recommend physical activity programmes that promote sustainable physical activity behaviour change.

### Wu and Hsieh (2006)

12 at-risk adolescents  
**Age range 11-17 years**  
**PRE-POST**  
Self-concept (Tennessee Self-Concept Scale) and life effectiveness (including the following subscales: time management, social competence, achievement motivation, intellectual flexibility, task leadership, emotional control, active initiative, self-confidence and locus of control) (Life Effectiveness Questionnaire).

- **28-day outdoor education programme.** Including rock climbing, ropes courses, horse riding, beach volleyball, sailing, canoeing, river-trekking, hiking, backpacking, first aid training and mountain climbing.
- **Paired samples t-test**  
  - Significant improvement in physical self-concept ($p = 0.01$).  
  - Significant improvements in most of the life effectiveness domains ($p < 0.05$).

### Sport and skill-based programmes

**Goodway et al (1996)**  
59 at-risk children  
**Age 4 years**  
**RCT**  
Perceived competence and social acceptance (Pictorial Scale of Perceived Competence and Social Acceptance).

- **12-week motor skill intervention.** Sessions last 45 minutes and included sustained activity, skill instruction and closure. Children in the CON group received their usual prekindergarten programme, which consisted of free play with motor skill equipment.
- **Repeated measures ANOVA**  
  - Improvements in perceived physical competence ($p = 0.01$). Perceived social acceptance increased in both INT and CON groups ($p = 0.03$).

**Tester et al (1999)**  
445 at-risk children and 546 at-risk adolescents  
**Age range 6-11 years and 12-16 years**  
**PRE-POST**  
Self-esteem (self and school, self and others, self-worth, self and home and overall) (Song and Hattie Self-Concept Scale).

- **Duration of the programme varied from two 40 minute sessions for 14 weeks to three 90 minute sessions for 4-weeks.**  
  - Through the medium of basketball and other sports at-risk youth are taught preparation for life-skills, such as realistic goal setting, strategies to address conflict,  
- **No details provided.**  
  - Authors report a 44% and 18% improvements in overall self-esteem in children and adolescents, respectively (no statistics were reported).

</thead>
</table>
| Bonnette et al (2001) | 80 at-risk adolescent boys  
Age range 10-13 years | QEXP | Global self-worth (Self-Perception Profile for Children). | Two 3-week sport and skill-based camps. Boys allocated to sports skills instruction (SSI) or sports skills instructions plus initiative (SSI+) groups. The programme was delivered at an outdoor summer camp five times/week for three weeks. Boys in the SSI group participated in skill-related drills to improve technique, modified and regulation games. Boys in the SSI+ group also participated in initiative games and sessions involved a student-centred approach. | ANOVA | No significant change in global self-worth ($p > 0.05$). |
| Palermo et al 2006 | 16 children with social cognitive and disruptive behaviours  
Age range 8-10 years | RCT | Domains of temperament- intensity, adaptability and mood regulation (Cary Temperament Scale). | 10-month karate programme with a frequency of three lessons/week. Classes included no actual fighting but followed a framework including a warm-up, the practice of skills and mimicking of combat situations. | Mann-Whitney t-test | Significant improvements in intensity ($p = 0.000$), adaptability ($p = 0.27$) and mood regulation ($p = 0.036$) in INT group. |
| Maiano et al (2007) | 24 adolescent boys with conduct disorders  
Age range 11-13 years | QEXP | Physical self-concept (overall physical self-worth, physical condition, sport competence, physical attractiveness and physical strength) and global self-esteem (Physical Self-Inventory). | Boys allocated to three groups: inter-establishment basketball (IEBB), integrated scholastic basketball (ISBB) and adapted physical activity COMP group. Boys in the IEBB and ISBB groups participated in basketball competitions for 18-months. Boys in the COMP group participated in a traditional | Repeated measures ANOVA | No significant changes in overall physical self-worth ($p = 0.24$, ES = 0.12), physical condition ($p = 0.06$, ES = 0.18), sport competence ($p = 0.58$, ES = 0.07), physical attractiveness ($p = 0.87$, ES = 0.04), and physical strength ($p = 0.53$, ES = 0.08) or global self-esteem ($p = 0.24$), ES = 0.12). |
An adapted physical activity program combining various numerous activities, such as tennis, volleyball, wrestling, and basketball.
