Running title: Potentially ambiguous AUDIT items

Key words: tertiary, students, AUDIT, epidemiology, screening

Word count: 1,977 (Abstract: 70)
ABSTRACT

Aim: To test for the possibility that tertiary students misinterpret certain items on the Alcohol Use Disorders Identification Test (AUDIT). Method: Responses to alternative question wordings were compared with responses to standard items. Results: Alterations to items 5 and 9, so that consequences of drinking epitomised in these items were more specifically defined, resulted in markedly different response distributions to the item but the total AUDIT score was not changed Conclusion: Caution is necessary before using individual AUDIT items as measures of consequences in population surveys, and the possibility of false positives in total scores should be born in mind.
INTRODUCTION

In the late 1970s, the World Health Organisation (WHO) set about developing an instrument for the purpose of identifying individuals with hazardous or harmful drinking (WHO Expert Committee on Problems Related to Alcohol Consumption, 1980). The resulting Alcohol Use Disorders Identification Test (AUDIT) (Saunders and Aasland, 1987; Saunders et al., 1993) was found to have high specificity and sensitivity in identifying hazardous drinkers in clinical settings (see Allen et al., 1997 for a review). However, for certain groups, such as university students, its specificity was found to be lower (Fleming et al., 1991), such that the test identified a significant proportion (29%) of individuals as hazardous drinkers when they were not so considered by a clinical assessment (i.e. they were ‘false positives’).

The high false positive rate does not necessarily detract from the AUDIT as a screening instrument, if a clinical judgement can be used to confirm hazardous drinking. The AUDIT, however, has been employed in population surveys as an epidemiological measure of hazardous drinking levels (e.g., Fleming, 1996; Ministry of Health, 1999), and as an outcome measure in analytical studies with specific populations (e.g., Claussen, 1999; Kozyk et al., 1998). In these contexts, the specificity of the instrument is as important as its sensitivity. The AUDIT has been exhaustively studied in terms of its psychometric qualities and suitability for various subgroups. What has not been examined in any depth since the original development work is how those completing the AUDIT interpret the questions.

As part of an ongoing study of tertiary student alcohol consumption, we were interested in exploring aspects of student life that might be adversely affected by
hazardous drinking, including fulfilment of role expectations. Our initial experience using the AUDIT in a large self-completed survey of tertiary students (Kypri et al., under review) led us to speculate that there might be variation in respondents’ interpretations of certain items.

Comments made by students during the survey administration, indicated that items 5 and 9 had ambiguous meanings. For item 5, which asks “How often in the last year have you failed to do what was normally expected from you because of drinking?”, students indicated uncertainty as to the meaning of the question. For item 9, which asks “Have you or someone else been injured as a result of your drinking?”, the absence of an injury threshold (e.g., injury requiring treatment), raises questions as to what some respondents may include and others not. On the AUDIT, a score of eight or higher is considered to be indicative of hazardous drinking (Conigrave et al., 1995). Given the heavy weighting for item 9 - four points for an answer “yes, during the last year”, variation in what individuals consider worthy of reporting as injury, would have important implications for estimating the prevalence of hazardous drinking in a population.

We sought to investigate interpretations of AUDIT items, to generate testable hypotheses concerning item wording, and to measure the effect of modifying items 5 and 9, on item scores and the estimated prevalence of hazardous drinking among tertiary students.
METHODS

Focus group studies

Advertisements were placed on notice boards at the University of Otago in Dunedin, New Zealand and at the student job service, for students aged 17-25 years who drank alcohol “most weeks”, to participate in “a study of student drinking”. A $20 music voucher was offered as reimbursement for participating in a two-hour focus group on drinking, use of health services, and interpretation of AUDIT items previously identified as ambiguous. Seven focus groups were formed, comprising 31 students (20 females and 11 males). Item 5 was displayed and participants were asked to describe the kinds of things they considered in making their response. Item 9 was presented and participants were asked to say what they counted as injury. Students were asked in turn for their views, and group discussion of possible improvements to wording followed.

For item 5, 14 focus group participants said they considered problems they might experience after a heavy night drinking, e.g. missing class the next day or failing to complete an assignment due to a hangover. The remaining 16 said they based their answers on experiences they had while drinking, e.g. behaving in an unruly manner, or stumbling, because of the acute effects of intoxication.

For item 9, 17 participants said they considered only injuries that required medical attention of some description. Eleven participants said they counted relatively minor injuries, for example, grazes or bruises they woke up with after a night of heavy drinking. The remaining two participants took the word injury to include verbal insults that might hurt another person’s feelings.
The focus group research led us to generate hypotheses concerning the wording of AUDIT items 5 and 9. In respect to item 5, concerning the failure to fulfil role expectations, on the basis of focus group results we constructed a modified item to examine specific instances of such failings. The standard wording of item 5 was followed by: “For example: (a) been late for class; (b) missed a class; (c) failed to complete an assignment on time; (d) been late for work; (e) missed practice or training for a sport; (f) let down a friend; (g) let down a family member”. These examples were derived from focus group discussion and appear to cover four major domains in which tertiary students might be considered to have role expectations: academic commitments (a, b, c), part-time work (d), sport (e), personal and family relationships (f, g). The response categories were the same as for the original AUDIT item. For responses (a) to (g), the highest frequency was taken as the value for the modified item 5. We hypothesised that by providing examples of the behaviours of interest and thereby discouraging an interpretation in terms of acute effects (e.g. disinhibited behaviour), the mean score would be lower than that for the standard item.

For item 9, concerning alcohol-related injury, we sought to specify a level of injury that required medical attention, and to distinguish injuries experienced by the respondent versus those sustained by others as a result of the respondent’s drinking. For the purpose of specifying the level of injury severity and determining who sustained the injury referred to in item 9, the following questions were asked: “As a result of your drinking, have you suffered an injury that required medical attention (e.g. at a hospital, medical centre, your GP’s office, or Student Health)?”, and “As a
result of your drinking, has someone else suffered an injury that required medical attention (e.g. at a hospital, medical centre, your GP’s office, or Student Health)\?”.

The highest value response to these two questions was taken as the value for the modified item 9. We hypothesised that, given the higher threshold for injury, the score on our modified item would be lower than that for the standard item.

Survey of student drinking and related harm

To test these hypotheses we included the standard AUDIT and the modified AUDIT items in a survey of a large sample of tertiary students in Dunedin. The sample and data collection procedures are described in a paper reporting on that study (Kypri et al., under review). In summary, tertiary students completed surveys at the start of the first semester of the academic year (Time 1) and in the middle of the second semester (Time 2). The Time 2 data alone are utilised in the present study.

Of 1,748 forms received from students (97% of the those present at contact), 1,672 (96%) met minimum data requirements, i.e. a complete AUDIT, gender, and indication of recent alcohol use. These 1,672 cases were utilised for analyses presented below.

Modified AUDIT items, embedded in a 12-page health questionnaire, were prefaced as follows: “The following three questions may seem like a repetition of some asked earlier, but please answer these also. Please do not change your answers to earlier questions based on your answers here”. Responses to the original AUDIT items were compared with responses to the modified items. A total score was produced for the
AUDIT and modified AUDIT, and distributions of scores derived from these scales were compared. Paired t-tests were used to examine mean differences.

RESULTS
Table 1 shows that in response to the modified version of item 5, students more frequently reported failing to fulfil role expectations (59.9% versus 48.5%) as a result of their drinking. In contrast, reports of recent injury were markedly less common for the modified version of item 9 (11.3% versus 21.7%).

The mean score for the modified item 5 was 0.35 of a point higher than that for the standard item, \( t(1654) = 16.2, p<0.01 \). The modified item 9 mean score was 0.38 of a point lower than that for the standard item, \( t(1651) = -10.1, p<0.01 \). The total score derived from the modified AUDIT was 0.03 of a point lower than that derived from the standard AUDIT, but this difference was not statistically significant. Table 1 also shows that 65.3% of males and 55.3% of females scored eight or higher (Total = 59.2%) on the standard AUDIT. On the modified AUDIT, 65.5% of males and 56.5% of females scored eight or higher (Total = 60.4%).

DISCUSSION
Our first hypothesis was not supported by the results: reports of failure to live up to role expectations, were, in fact, more frequent for the modified version of item 5. Our second hypothesis was supported by the results: reports of alcohol related injury were
less frequent when it was specified that only injuries requiring medical attention were to be included. The combined effect of these two modified items was neutral in relation to total AUDIT scores and had minimal effect on the estimate of the prevalence of hazardous drinking.

Approximately half of the focus group participants gave unexpected interpretations of item 5. Rather than considering failure to fulfil role expectations, these students focused on behaviour that might have been out of character if they had been sober, e.g. stumbling or vomiting. Although this interpretation is technically a miscomprehension, it was sufficiently common to require a rewording of the question. By providing examples of failure to fulfil role expectations, memory was perhaps cued, thus resulting in a measure with greater sensitivity than the standard question.

How other populations might interpret item 5 is unknown. Given the changes in role expectations from adolescence through early and later adulthood (Bachman et al., 1997), it may be that this question is understood differently by older people or those in full-time work. Furthermore, if the AUDIT is to be used with school-aged youth, some investigation of this group’s interpretation of AUDIT items is advisable.

One objective of employing the AUDIT in a population survey (e.g., Ministry of Health, 1999), is to contribute to official and public understanding of alcohol related harm and to inform policy decisions. For the purpose of injury prevention, we want to be able to report the incidence of alcohol related injury that meets a specified minimum level of severity. An AUDIT scale including the modification to item 9 tested in this study would facilitate the collection of one-year injury incidence and
lifetime incidence data. Also, by splitting item 9 into two parts: injury to self and injury to someone else, one can make clearer statements concerning the incidence of alcohol related injury.

Our review of the literature identified the AUDIT as the best brief instrument available for the purpose of measuring the prevalence of hazardous drinking in a tertiary student population. Although we anticipated problems related to potential ambiguity of two items, the process of inquiry described in this paper revealed the AUDIT to be remarkably robust to varied item interpretations. It is, of course, possible that other AUDIT items are variably interpreted, and that interpretations vary across segments of the wider population. Our study also suggests that use of individual AUDIT items as indicators of particular alcohol related problems, (e.g. item 9 for the incidence of injury) may be problematic. We concur with Ivis and colleagues’ (2000) suggestion that there is merit in conducting research on the use of the AUDIT in population surveys.

ACKNOWLEDGEMENTS

This research was funded by the Alcohol Advisory Council of New Zealand, the Harold Richardson Trust, and the Health Research Council of New Zealand. The Injury Prevention Research Unit is jointly funded by the Accident Compensation Corporation and the Health Research Council of New Zealand. The first author is grateful for the support of the Health Research Council and a John Dobson Memorial Scholarship.
